

Random Forest

Introduction:

⇒ Random Forest is a bagging based technique.

⇒ How Random Forest Performs so well? It leads to low Bias and low Variance, as distributed data in same model leads to low variance.

⇒ Diff. b/w R.F. and Bagging:

① Bagging allows different models like LR, RF etc. as the base model. While RF uses decision trees only as the base model.

② Tree level column sampling is used in Bagging while RF uses Node level sampling.

OOB:

⇒ Out of Bag Evaluation means the samples which are never used in training any decision tree. These left rows are used in validation set.
